

MITTAL
SCHOOL OF BUSINESS

ACADEMIC TASK-1

Course Code:	MGN100M
Course Title:	Career Planning
Course Instructor:	Dr. Priyanka Mahajan
Academic Task no.	1
Name:	Harshita Gupta
Registration no.:	12616648
Class roll no.:	22
Section:	Q1P2629
Date of allotment:	August 20 th ,2026
Date of submission:	September 1 st ,2026
Max. Marks:	10

Acknowledgement

I would like to express my sincere gratitude to everyone who supported me in completing this Career Planning Project.

First, I am thankful to my teacher for providing me with valuable guidance, encouragement, and suggestions throughout the project. I am also grateful to my university for giving me the opportunity to explore different career options and understand the importance of proper career planning.

I would also like to thank my parents, family members, and friends for their constant support and motivation. Finally, I am thankful to everyone who directly or indirectly contributed to the successful completion of this project.

This project has helped me gain a better understanding of my interests, strengths, skills, and future career goals.

DECLARATION

I hereby declare that the project report is an original work carried out by me under the guidance and supervision of **Dr. Priyanka Mahajan** in partial fulfilment of the requirements for the completion of my assignment at **Mittal School of Business ,LPU**.

I further declare that this project has been undertaken solely for academic purposes and that the work presented in this report is based on my own efforts, research, analysis, and implementation. All sources of information, references, and materials used in the preparation of this project have been appropriately acknowledged.

1. Introduction: A Real-World Problem in Finance

Finance teams like whether in asset management, corporate finance, investment banking or retail banking are sinking in unorganised information related to quarterly filings, regulatory circulars, earnings-call transcripts, and client queries all comes faster as compared to human analysts who can realistically read and combine them. At the same time regulators and clients increasingly expect fast, customized, and clearly explained financial communication, not template text. This creates a huge gap between the volume and speed of information finance professionals must process and the human capacity available to process it accurately.

This is the real-world opportunity I have chosen to address through this reflection: how can a future finance professional use an emerging technology to close the gap between the total volume of financial information that must be read, summarised, and communicated, and the limited analyst time available to do it well - without compromising accuracy or submission ? The technology I have selected to address this problem is Generative AI, applied specifically to financial analysis, reporting, and client consultative workflows.

The rest of this report builds a complete picture of that opportunity: what Generative AI actually is, where it is already being used through finance, an original sample concept I have designed to apply it, a balanced view of its benefits and risks, and finally how learning to use it responsibly enhances my own path into a finance career.

2. Understanding Generative AI

Generative AI refers to a type of artificial intelligence systems that built primarily on large language models (LLMs) that can create new, original content such as summaries, text, code or structured analysis in response to a natural-language prompt, rather than simply grouping or obtaining existing data. Well-known examples such as OpenAI's ChatGPT, Humanics Claude, Google's Gemini, and finance-specific models such as BloombergGPT, which was trained specifically on financial documents and market data.

These models are trained on huge datasets to learn statistical patterns in language and increasingly, in numerical and tabular data at the technical level. When given a prompt for instance, "summarise the key risks disclosed in this 10-K filing in five bullet points" - the model project and gathers a logical, relatively suitable response drawing on the patterns it has learned.

Why Generative AI Matters Specifically for Finance

- Unorganized data processing: turning transcripts, long filings and news flow into organized, Accessible analysis.
- Natural language access to data: permitting non-technical staff "ask" complicated financial queries in plain English.
- Personalisation at scale: personalizing the same basic analysis into client's suitable language for very different audiences.
- Always on support: giving initial responses to routine client or internal questions outside business hours.

3.The Generative AI Landscape Across Finance Functions

Generative AI is a multiple use tool in finance because it is already being tested or implemented across almost every major function, from research to accordance to client facing guidance. The table below maps the main finance functions to how Generative AI is presently being applied within them, along with real organisations already using such tools, to ground the analysis in the actual state of the industry rather than speculation.

Function	How Generative AI Is Applied	Example Tools / Players
Investment Research	Summarising earnings calls, research reports and annuals report into concise briefs in seconds instead of hours.	Bloomberg GPT, Morgan Stanley AI @ Morgan Stanley Assistant
Risk Management	Drafting risk accounts, stress-test commentary and scenario summaries from organized risk data.	S&P Global AI tools , Moody's
Fraud Detection & adherence	Generating human-readable explanations of suspicious transactions and drafting suspicious-activity reports (SARs).	Mastercard Decision Intelligence, ComplyAdvantage
Financial Reporting	Drafting first versions of MD&A segments, endnotes, and variance commentary for finance teams to review.	Workiva, Microsoft Copilot for Finance
Client Advisory / Robo-Advisory	Forming personalised portfolio explanations and financial planning overview for retail clients at different levels.	Morgan Stanley, Wealthfront-style robo-advisors
Credit Underwriting	Converting organized credit-model outputs into plain-language justifications for loan officers and applicants.	Upstart, Zest AI
Internal Knowledge & Training	Chat based assistants that answer employee queries against internal policy and product documents.	Internal LLM copilots (JPMorgan's LLM Suite, Goldman Sachs GS AI Assistant)

What stands out throughout this landscape is a common pattern: Generative AI is rarely used to make the final financial decision. Instead, it is used to shorten the time between raw data and a human reviewed judgement composing the first version of a summary, memo, or explanation that a skilled professional then checks, edits, and approves. This human in the loop pattern is central to how the technology is being responsibly accepted in a heavily governed industry like finance.

4. Practical Application: The AI Finance Analyst Co-Pilot

From theory to practical, I created an original prototype/model called the AI Finance Analyst Co-Pilot an organized workflow with a junior analyst, financial planning intern, or small advisory firm could practically build today using current tools such as ChatGPT, Claude AI for text generation, connected to a company internal filings and market data inputs. It is not a new piece of software but a structured way of using generative AI securely inside a real finance workflow.

4.1 The Problem It Solves: Before every client meeting or investment board discussion, an analyst typically needs to

- (a) review the latest company filings and news,
- (b) update a valuation or risk outlook,
- (c) convert that into a clear, client suitable explanation.

Doing all three well, for multiple companies or clients uniformly consumes much more time than most analysts, especially juniors and interns that are given. The AI Finance Analyst Co-Pilot is created specifically to compress step (a) and step (c), while keeping the analyst fully in control of step (b), the actual judgement.

4.2 Prototype Workflow

- **Data Intake:** Upload the latest filing, earnings call transcript (written record), or research note into the AI tool together with a fixed "house style" template (tone, required sections, disclaimers).
- **Structured Summarisation:** Ask the AI to pull out key financials, management commentary, and risk factors into a standard format not free-form narrative, so nothing important is missed.
- **Analyst Review & Judgement:** The analyst checks every extracted figure against the source document and corrects errors then adds their own view, the step where real financial judgement is practiced and where AI is purposely unreliable to decide.
- **Audience Translation:** Once authorized, the AI rewrites the same underlying analysis into two versions firstly, a technical version for the investment committee secondly, a plain language version for retail clients.
- **Audit Trail Logging:** Every AI-generated draft and every human edit is dated and stored, so the firm can show a regulator exactly what the AI created versus what a human modified.

4.3 Sample Prompt and Output (Illustrative)

instruction given to the model: "Using the enclosed quarterly filing, list the three largest revenue drivers, the two largest disclosed risks, and one sentence comparing this quarter to the previous quarter. Use only figures present in the document."

Illustrative AI output (to be verified by the analyst before use): a three-bullet revenue analyse, a two-bullet risk overview, and one comparison sentence that each bullet under fifteen words, in the firm's house style, ready for the analyst to check against the source filing and approve or correct.

4.4 Why This Design Is Deliberately Conservative

Unlike an entirely automated "AI analyst," this model keeps every numerical decision and investment view under mandatory human review (Step 3), and keeps a full audit track (Step 5). This is a calculated design choice: finance is a field where an AI generated error has direct monetary and regulatory outcomes, so the innovation here lies in how the workflow is organized for safe implementation, not in eliminating humans from the loop.

5. Expected Benefits and Limitations

Every developing technology carries trade-offs, and finance is a field where those trade-offs matter more than most because errors carry direct financial and legal consequences

Expected Benefits	Limitations / Risks
Reduces research and reporting time from hours to minutes, liberating analysts for judgement heavy work	the model can generate credible looking but factually wrong figures
Makes complicated financial information available to non-expert clients through simple language summaries	Data confidentiality risk when supplying owned financial data into external AI tools
Enhances consistency of internal records (risk memos, compliance notes)	Regulatory uncertainty most financial regulators have pending AI-specific rules
Enables 24/7 first line client doubt handling, reducing pressure on advisory teams	clarity gap: hard to validate an AI-influenced credit or investment decision to a regulator
Reduces the cost of producing customized financial content for a large client base	Possible expansion of bias present in historical financial or lending data

6.Critical Analysis: Future Impact, Case Studies, and Regulatory Challenges

V

6.1 Where the Industry Is Already Headed

Multiple large financial institutions have moved beyond pilots into live deployment. JPMorgan Chase built an internal generative AI assistant, referred to publicly as the LLM Set, to assist hundreds of thousands of employee's draft documents and analyse data. Morgan Stanley collaborated with OpenAI to build an internal assistant that provides financial advisors instant, natural-language access to the firm's research library. Bloomberg developed BloombergGPT, a large language model trained particularly on decades of financial data, to enhance tasks like sentiment analysis and named-entity identification within finance. These are not experimental toys - they are production systems inside some of the most heavily controlled financial institutions in the world, which signals that the industry evaluates the risk adjusted advantage to already be positive when properly supervised.

6.2 The Challenges That Come with This Shift

In spite of this progress, three types of risk deserve serious consideration rather than blind optimism. First is the delusions risk: language models can produce smooth, fluent, confident, and completely made-up numbers or facts, which is uniquely unsafe in finance where a single wrong figure in a client report can cause real financial loss. Second is the explainability and legal risk: financial regulators such as India's SEBI and RBI, the US SEC, and the EU's upcoming AI Act increasingly needed by firms to be able to explain how a decision impacting a client was reached, and "the AI model produced it" is not presently a passable explanation on its own. Third is data security and confidentiality risk: supplying owned trading strategies, private financials, or client personal data into external AI tools without proper safeguards can expose a firm to data leaks or insider-information leaks, which is why most major banks now use privately hosted models rather than public consumer chatbots for confidential work.

6.3 My Assessment of the Next Five to Ten Years

I expect the analyst role in finance to shift from being the primary producer of first draft analysis to being the primary reviewer, judge, and communicator of AI-assisted analysis nearer to an editor in chief than a sole author. This does not remove the need for strong technical finance skills; if anything it raises the standard, because the analyst must be skilled enough to catch a subtle AI error that sounds confident and correct. My conclusion is therefore balanced rather than purely passionate: Generative AI is a real productivity multiplier for a finance career, but its safe use depends entirely on the human judgement, suspicion, and regulatory awareness applied around it which is precisely the professional maturity this Career Planning course is designed to build.

6.4 Two Illustrative Mini Case-Studies

Case Study 1 - Investment Research at Scale: An average sized asset management firm pilots a generative AI tool to preview every company's quarterly filing the moment it is released, producing a one-page structured summary within minutes. Analysts report that their day now

starts with review and challenge of an AI draft rather than starting from a blank page, reducing initial research time significantly - but the firm instructs that no summary can be sent externally until a named analyst has personally approved every number against the source filing, directly reflecting the human in the loop principle discussed above.

Case Study 2 - Retail Banking Client Support: A retail bank implements a generative AI chatbot to answer routine account and product queries, intensifying anything involving a complaint, a large transaction to a human advisor. Customer satisfaction results for simple queries improve because response time drops from hours to seconds, but the bank discovers early on that the model sometimes misrepresents fee structures with total confidence, reinforcing why a strict rise and disclaimer policy and regular human audits of chatbot transcripts is fixed in a regulated setting.

6.5 Traditional Approach vs. Generative-AI-Assisted Approach

The comparison below makes solid the shift described throughout this section, contrasting how a routine finance task was traditionally done against a well-managed generative

Task	Traditional Approach	Generative-AI-Assisted Approach
Reading a 200-page annual report	Analyst physically reads and highlights over several hours	AI produces a organised first-pass summary in minutes; analyst verifies and adds judgement
Explaining portfolio performance to a client	Advisor physically drafts a bespoke explanation for each client	AI drafts a personalised explanation from the same underlying data; consultant reviews and sends
Answering a routine policy question internally	Employee shared drives or emails a colleague and waits for their answers	AI chatbot answers instantly from listed internal documents, with a source reference
Drafting a risk-committee memo	Analyst writes the narrative from initial stage after building the model	AI drafts the reports from the analyst's finished model outputs; analyst edits and owns the final view

7.SWOT Analysis: Generative AI in Finance

A SWOT structure helps summarise the critical analysis above into a decision-ready view.

STRENGTHS	WEAKNESSES
Severely faster research, reporting, and client-communication cycles; works 24/7 across languages.	Prone to delusions on numeric data; not inherently auditable or explainable; needs constant human review.
OPPORTUNITIES	THREATS
Democratizes high-quality financial understanding for smaller firms and retail investors; new hybrid "AI + analyst" career paths arising.	Constricting regulation (SEC, RBI, SEBI, EU AI Act); image risk from AI errors in high-stakes financial decisions; cybersecurity exposure.

8.Alignment with My Career Aspirations and Employability

My career interest lies in finance, and Generative AI is becoming directly applicable to almost every entry point into the field like equity research, corporate finance, financial planning and analysis (FP&A), risk, and retail/wealth advisory. Job postings for roles such as financial analyst, credit analyst, and associate at leading banks and asset managers increasingly refer to ease with AI-assisted research tools beside traditional skills like financial modelling and valuation. By understanding not just how to use these tools but how to analyse, verify, and safely implement their output as displayed through the AI Finance Analyst Co-Pilot design in Section 4 - I position myself as a candidate who can help a finance team to take up these tools responsibly, rather than one who needs to be trained on both finance fundamentals and AI literacy from scrape after being hired.

This also sharpens what kind of finance professional I want to become: less a person who spends most of their time physically assembling data, and more a person who spends their time on decision and analysing what the numbers mean, queries about AI-generated output, and discussing conclusions clearly to decision-makers and clients. That is a more calculated, higher-value role, and building fluency with Generative AI now is how I intend to reach it earlier in my career than equals who treat it as an afterview.

8.1 Skills This Technology Rewards

Considering on Sections 4 and 6 together, three definite skills stand out as growing in worth for a finance professional in an AI-assisted workplace that are verification skill (the ability to quickly and thoroughly check an AI-generated figure or claim against the original source), translation skill (turning a technical analysis into a clear explanation for a beginner audience, which the AI can draft but a human must own), and judgement skill (deciding what the numbers actually mean for a decision, which remains the one part of the workflow in Section 4 that is purposefully never allocated to the AI). Building these three skills purposefully, rather than assuming they will develop automatically, is the core of my roadmap in Section 9.

9. Personal Skill-Building Roadmap

1. Build finance fundamentals first: keep honing essential skills like financial statement analysis, valuation, and Excel- so I can judge AI output decisively rather than accepting it blindly.

2. Practise AI-assisted analysis intentionally: use AI tools on real case studies during my degree (e.g., summarising a company's annual report, then verifying every figure myself) to build the reviewer skill described in Section 6.3.

3. Learn the safeguards, not just the tool: study the basics of data confidentiality, model risk, and relevant financial regulation (SEBI/RBI guidelines on AI where applicable) so I understand the complex side, not only the productivity side.
4. Build a portfolio artifact: make an model like the AI Finance Analyst Co-Pilot into a real mini-project (even a simple prompt template and sample output) that I can discuss clearly in internship and placement interviews.
5. Seek exposure early: looking for internships or student projects at firms already piloting generative AI in finance, to gain first-hand exposure before I graduate.

In short, Generative AI does not swap the finance career I am aiming for - it reforms which skills make me competitive within it, shifting the premium from physical data-gathering toward judgement, verification, and clear communication.

10. Conclusion

Generative AI addresses a real problem of growing gap in finance between the volume of information that must be read, verified, and communicated, and the limited analyst time available to do it well. Through the AI Finance Analyst Co Pilot concept, this report has shown a practical, human monitored way to apply the technology to real finance workflows, charted its use across major finance functions, weighed its genuine benefits against serious and finance specific risks such as delusion and regulatory explainability, and set out a personal plan for building the judgement or verdict first skill set that a future finance career will increasingly reward. Approached critically, carefully and with strong human supervision, Generative AI is less a threat to my chosen career path and more one of the clearest opportunities within it.
